

**What was sent is a plan for an enterprise B2B procurement platform** — the kind of system a mid-size FMCG manufacturer would build to manage sourcing raw materials, packaging, and logistics vendors, with AI doing demand forecasting, price intelligence, risk scoring, and logistics optimization. That's a genuinely different product from what has already been built: an informal-market broker where local sellers list goods over WhatsApp and a middleman vets them by hand.

Some of the vocabulary maps cleanly onto what already exists, just under different names:

| B2B concept                                                                              | What's already built                                                            |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Supplier lifecycle<br><i>Identification → Qualification → Due diligence → Onboarding</i> | Supplier lifecycle<br><i>New contact → form → APPLICATIONS review → APPROVE</i> |
| Category structure                                                                       | Category structure                                                              |
| Raw materials, packaging, indirect, services                                             | Free-text category field per listing                                            |
| Supplier evaluation                                                                      | Supplier evaluation                                                             |
| Scorecard: price, quality, delivery, compliance, etc.                                    | Not built — approve/reject is binary, no scoring                                |
| "AI Procurement Engine"                                                                  | "AI Procurement Engine"                                                         |
| Demand forecasting, price intelligence, risk scoring, logistics optimisation             | Not built — no forecasting, matching, or optimisation of any kind               |

Two of those rows listed above, especially the lifecycle or categories are cheap to strengthen right now. If you want I can formalize the free-text `category` field into a fixed set (raw materials, packaging, indirect, services, with sub-categories), and add a few scorecard fields to the seller application (delivery reliability, lead time) that the middleman can rate over time.

The bottom row — an actual "AI procurement engine" which does demand forecasting, price intelligence, and logistics optimization — is not a feature I can bolt onto this WhatsApp bot in an afternoon. That's a data-pipeline-and-modeling project in its own right, usually built *after* a platform has months of real transaction history to learn from — building it now, with zero data, would mean shipping something that just guesses.
